Model Checking

SOWMIYA R/AP/AI&DS/23ITT203 OBJECT ORIENTED SOFTWARE ENGINEERING/SNSCE

What is Model Checking?

Definition:

- Model checking is an automated technique used to check if a software system behaves correctly by exploring all possible states the system can be in.
- It answers the question: "Does my software always behave correctly, no matter what inputs or ulletsituations occur?"

How Model Checking Works

Create a model of your software lacksquare

(e.g., a flowchart, a diagram, or a state machine that represents how your system behaves)

Define properties or rules to check \bullet

(e.g., "The system should never crash", or "The door should never open while the elevator is moving")

Use a model checker

(a software tool that automatically checks all possible behaviors against those rules)

If a rule is violated, the model checker shows a counterexample (an error path). \bullet

Real-Life Example: Traffic Light System

Scenario:

You are building software for a **traffic light** that cycles like this:

 $\text{Red} \rightarrow \text{Green} \rightarrow \text{Yellow} \rightarrow \text{Red}...$ \bullet

You want to check:

- The light never turns green right after yellow \bullet
- The light **never skips a color** \bullet

How Model Checking Applies

Model: You model the traffic light as a **state machine**:

States: Red, Green, Yellow

Transitions: Red \rightarrow Green, Green \rightarrow Yellow, Yellow \rightarrow Red

Rules to check:

It must always go Red \rightarrow Green \rightarrow Yellow \rightarrow Red

It must never go Red \rightarrow Yellow (skip green)

Model Checker: The tool checks **all possible sequences** of state changes, and if it finds any

incorrect path (like Red \rightarrow Yellow), it shows that as a problem.

In Object-Oriented Software Engineering

In OOP, systems have:

Classes and **objects**

State changes (when an object variable changes)

Interactions between objects (e.g., user login, transaction, notification)

- Model checking helps by:
- Modeling object behaviors as **state machines**
- Checking if methods and object states follow correct rules
- Verifying safety properties like "user must be logged in before accessing data"
